Next.js App Router

Role-based access

Prepared August 2026 · v0.1

01 Sitemap

Every screen an employee can reach, and how they connect. After logging in, the app is organized around five bottom-navigation tabs (Home, Attendance, Checklists, Audits, Communication) plus Profile, which stays reachable to every account regardless of role so there's always a way to sign out.

Fig. 1 — Full screen hierarchy. Dashed = built but currently unreachable from navigation.

ROUTE	SCREEN	NOTES
/login	Login	Email + password. Public — the only route reachable while signed out.
/home	Home	Assigned sites, notification bell, quick clock in/out.
/sites/[siteId]	Site Details	Reached by tapping a site card on Home.
/attendance	Attendance	Site picker (if assigned to more than one), clock card, history.
/checklists	Checklists	Pending/submitted list. Supervisors with review access see the whole company's submissions.
/checklists/[id]	Checklist Detail	Fill subtasks/notes/photos and submit, or a read-only view for non-owners.
/audits	Audits	List of submitted and assigned audits.
/audits/[auditId]	Audit Detail	Ratings, marks, photos.
/audits/new	New Audit	Start a new audit submission.
/communication	Comm Log	Open/Closed tabs, listing threads the employee is a participant in.
/communication/[id]	Chat Thread	Live chat (Firestore), image attachments, Close/Reopen.

ROUTE	SCREEN	NOTES
/communication/new	Send	Compose a message and pick specific recipients at the company.
/profile	Profile	Employee details, assigned Access Role and what it grants, Log Out. Always reachable.
/profile/change-password	Change Password	Built, but temporarily unlinked from navigation.

Role-gated navigation. Which of the five main tabs actually appear depends on the signed-in account's Access Role (configured in the Admin Dashboard's Roles & Access). A Client role, for example, only sees Checklists (images only), Communication, and Profile — Home, Attendance, and Audits are hidden entirely rather than shown and blocked.

02 User Flow — Login

A single credentials form. Where the employee lands afterward depends entirely on their role's permissions, not a hardcoded destination.

Fig. 2 — Login always resolves to whichever tab the role actually grants, e.g. Attendance for a role without Home access — never a hardcoded screen a role can't use.

What can stop a login: wrong credentials · no employee profile linked to the account · the account's role has zero app-side permissions ("This account doesn't have mobile app access — use the Admin Dashboard instead").

03 User Flow — Clock In / Clock Out

Location is only requested at the moment of clocking in or out — not at login — and every site an employee works is tracked independently, so clocking in at one site never affects another.

Fig. 3 — Each site keeps its own independent record for the day, keyed by site — clocking out at one site never closes or interferes with another site's open clock-in.

Location outside the site's geofence doesn't block the clock in/out — it's recorded on the attendance record (with a resolved place name via GPS reverse-geocoding) for the admin to see, rather than locking the employee out in the field.

04 User Flow — Checklists

Checklists are delivered automatically on the schedule set per company — no manual "assign for today" step required once an employee is linked to a template.

Fig. 4 — A Supervisor-type role with "review all" access sees every employee's submitted checklists company-wide, not only their own.

Some roles (e.g. Client) only get an **images-only** view — a photo gallery of the completed checklist, without subtasks, notes, or the ability to submit.

05 User Flow — Communication

A private, participant-only messaging thread. Only the people explicitly picked when a thread is started can ever see or reply to it — not even an Admin account can see a thread they weren't added to.

Fig. 5 — Recipient list is fixed at creation. Access control is enforced twice — once on the thread's metadata (Postgres), once on the live message stream (Firestore) — so a party removed from the picker never sees the thread at all, in either the list or the chat.

Any recipient can reopen a closed thread later, and tapping an attached image opens a full-screen preview.
